The research report highlights the growth potential of the global Isocitrate Dehydrogenase Inhibitors market. Isocitrate Dehydrogenase Inhibitors are expected to show stable growth in the future market. However, product differentiation, reducing costs, and supply chain optimization remain crucial for the widespread adoption of Isocitrate Dehydrogenase Inhibitors. Market players need to invest in research and development, forge strategic partnerships, and align their offerings with evolving consumer preferences to capitalize on the immense opportunities presented by the Isocitrate Dehydrogenase Inhibitors market.

Isocitrate dehydrogenase (IDH) (EC 1.1.1.42) and (EC 1.1.1.41) is an enzyme that catalyzes the oxidative decarboxylation of isocitrate, producing alpha-ketoglutarate (?-ketoglutarate) and CO₂.

Specific mutations in the isocitrate dehydrogenase gene IDH1 have been found in several brain tumors including astrocytoma, oligodendroglioma and glioblastoma multiforme, with mutations found in nearly all cases of secondary glioblastomas, which develop from lower-grade gliomas, but rarely in primary high-grade glioblastoma multiforme. Patients whose tumor had an IDH1 mutation had longer survival. Furthermore, mutations of IDH2 and IDH1 were found in up to 20% of cytogenetically

normal acute myeloid leukemia (AML). These mutations are known to produce (D)-2-hydroxyglutarate from alpha-ketoglutarate. (D)-2-hydroxyglutarate accumulates to very high concentrations which inhibits the function of enzymes that are dependent on alpha-ketoglutarate. This leads to a hypermethylated state of DNA and histones, which results in different gene expression that can activate oncogenes and inactivate tumor-suppressor genes. Ultimately, this may lead to the types of cancer described above. Isocitrate dehydrogenase inhibition technology can be effectively applied to the cancer market.
