The pressure generated by the roller press through the opposite operation of the upper and lower rollers compresses the coating surface of the electrode. The electrode is transformed from a fluffy state to a dense state under high pressure, and the roller pressure is significantly crucial for energy density. The significance of rolling is to compact the electrode and improve the energy density of the battery. After the coating and drying of the electrode in the previous process, the peeling strength between the active substance and the foil is very low. At this time, it is necessary to roll it to enhance the bonding strength between the active substance and the foil to prevent peeling during electrolyte immersion and battery use. An appropriate compaction density can increase the discharge capacity of the battery, reduce internal resistance, reduce
