Live and inactivated vaccines are both important tools in preventing diseases in ruminant animals such as cattle, sheep, and goats. Live vaccines contain weakened forms of the pathogen, stimulating a strong immune response similar to natural infection without causing disease. These vaccines often provide rapid and long-lasting immunity with fewer doses required but may pose a risk to immunocompromised animals. In contrast, inactivated vaccines contain killed pathogens that cannot cause disease but still trigger an immune response. While generally safer for all animals, they may require multiple doses or boosters for effective immunity. The choice between live and inactivated vaccines depends on factors like disease prevalence, animal health status, and desired duration of immunity, with veterinarians tailoring vaccination programs to optimize herd health and productivity. Regular vaccination plays a critical role in disease prevention and control within ruminant populations.
