Growth factors for cell culture are essential proteins or peptides that promote cell survival, proliferation, differentiation, and metabolism in vitro. They are used to maintain the health and functionality of cultured cells by mimicking the signals they would typically receive in the body. These factors can be specific to certain cell types or have broader effects across various cell lines. Common examples include Epidermal Growth Factor (EGF) for epithelial cells, Fibroblast Growth Factor (FGF) for mesenchymal cells, and Insulin-like Growth Factor (IGF) for enhancing growth and differentiation. They are typically added to cell culture media to support the growth of primary cells, stem cells, or transformed cell lines, and can also influence cell behavior such as migration, gene expression, and tissue formation.
