Abstracts

The global Melanocyte-Stimulating Hormone Receptor market size is predicted to grow from US\$ million in 2025 to US\$ million in 2032; it is expected to grow at a CAGR of %from 2026 to 2032.

Melanocyte-stimulating hormone receptor is a research-grade protein product prepared around a melanocyte membrane receptor and belongs to the seven-transmembrane G protein-coupled receptor class. The commercial product is generally not supplied as a visible bulk material, but as microgram-scale lyophilized powder, buffered solution, membrane-displayed protein particles, over-expression cell lysate, or stable receptor-expressing cells. Its core composition is the human or animal receptor amino acid sequence, often carrying tags such as His or GST; some formats also contain membrane lipids, virus-like particle envelopes, or storage buffer systems. The receptor recognizes melanocyte-stimulating hormones and related peptide signals, and after activation regulates melanin production through adenylate cyclase and cAMP signaling. Production requirements focus on transmembrane expression, correct folding, membrane localization or display, purity, batch consistency, and low-temperature stability. Common expression routes include cell-free, *E. coli*, yeast, insect cell, and mammalian cell systems. It is mainly used in receptor drug screening, antibody development, immunogen preparation, pigmentation mechanism research, melanoma-related research, and positive controls for assay development.

The market opportunity for Melanocyte-stimulating hormone receptor products is driven by the upgrading of membrane protein research tools, deeper investigation of pigmentation biology, increasing melanoma-targeted research, and early-stage drug discovery demand for functional receptor materials. Traditional soluble fragments often cannot fully reproduce the native conformation of a multi-pass membrane receptor,

while membrane-displayed proteins, virus-like particles, and stable receptor-expressing cell lines better approximate the natural membrane environment. These formats are better suited for antibody discovery, ligand screening, and functional validation. As early discovery teams in pharmaceutical and biotechnology companies pay closer attention to receptor selectivity, conformational specificity, and cell-based functional readouts, the value of high-quality, low-volume products is expected to increase.

The main restraints lie in production difficulty, quality consistency, and limited demand scale. This receptor is a multi-pass membrane protein, making expression level, folding quality, membrane localization, and activity retention more difficult to control than for ordinary soluble proteins. Products from different suppliers vary substantially in expression system, tag position, sequence coverage, purity, and recommended application, which makes direct price comparison difficult. Downstream customers usually purchase by project, with small order sizes and demand cycles influenced by publications, drug programs, and research budgets. As a result, the market can grow steadily but is unlikely to become a bulk standardized reagent market.

Downstream demand will gradually shift from simple antigens and positive controls toward more native-like membrane-displayed products, stable expression cell lines, and functional screening systems. Skin biology, pigmentation, inflammatory modulation, and melanoma research will continue to support basic research demand, while drug discovery and antibody development will place more emphasis on verifiable receptor expression, low background signals, and batch-to-batch consistency. Purchasing decisions are expected to move beyond price comparison and increasingly evaluate expression format, conformational fidelity, validation data, delivery stability, and technical support capability.
