The global Metal Bipolar Plate for Electrolyzer market size is predicted to grow from US\$ million in 2025 to US\$ million in 2032; it is expected to grow at a CAGR of % from 2026 to 2032.

Green hydrogen technology is centered around two processes: electrolytic splitting of water into hydrogen and oxygen (electrolysis) with the external input of energy, and the use of energy from the reverse reaction (fuel cell). Both run in a so-called stack. This stack represents the heart of the technology, in which the electrochemical reactions take place. The main component of this stack is the bipolar plate, which consists of two very thin metallic plates welded together and is used several hundred times per single stack. As the term itself suggests, the bipolar plate serves as a carrier for the two poles of the fuel cell: the negative anode plate and the positive cathode plate. The plates are responsible for the distribution and reaction process of the gases in the fuel cell as they control the chemical reaction of hydrogen and oxygen to electrical energy and water. They also ensure the electrical contact between the individual cells and separate the membrane electrode assemblies (MEA). The membrane electrode unit serves as a semi-permeable membrane, which is only permeable to protons and forces the electrons emitted by the hydrogen from the anode via an electrical device to the cathode. The remaining protons migrate through the membrane and finally react with the oxygen atoms to form water. A cooling medium for temperature control of the individual cells is passed between the tightly welded individual plates. The channel structure of the so-called flow field serves as the contact surface between hydrogen and oxygen and can be seen in the opening image.
