Desiccants are commonly utilized to induce dryness and reduce the moisture in the environment. They are considered hygroscopic substances that induce or sustain a state of dryness (desiccation) in their vicinity. Commonly encountered pre-packaged desiccants are solids that absorb water. Desiccants are employed to eliminate excessive humidity that would degrade or destroy products sensitive to moisture. It contains adsorbents with tiny pores of a precise and uniform size used for gases and liquids. Commonly used desiccants are silica gel, activated alumina, activated carbon, molecular sieves, montmorillonite clay, and aluminosilicate minerals (ceramic balls) or reactive γ -alumina (tabular alumina).

Mineral desiccant is produced through the refining process, which helps in the removal of impurities and moisture. Based on process type, the mineral desiccant market can be bifurcated into silica gel desiccant and clay desiccant. Silica gel desiccant has high specific surface area, which allows it to adsorb water readily. Thus, it is useful as a drying agent. Clay desiccant is made up of montmorillonite clay, which is a naturally occurring porous adsorbent. It is chemically inert and non-corrosive. It is primarily composed of calcium and magnesium aluminum silicates.
