The global Multilayer Common Mode Noise Filter market size is predicted to grow from US\$ 119 million in 2025 to US\$ 216 million in 2032; it is expected to grow at a CAGR of 9.0% from 2026 to 2032.

A multilayer common-mode noise filter is an electronic device used in electronic circuits to suppress common-mode noise. Common mode noise refers to noise that appears on two pins of a circuit at the same time, usually caused by electromagnetic interference, ground return flow and other factors. This type of filter uses multiple levels of filter components, such as inductors, capacitors or magnetic beads, to improve the suppression effect of common mode noise.

Multi-layer common mode noise filters usually adopt a multi-level structure, with multiple filter elements nested together to enhance filter performance. These layers of filtering elements introduce impedance into the circuit, effectively suppressing the propagation of common-mode noise. Common filtering components include inductors, capacitors, and magnetic beads, and their selection depends on the application requirements and operating frequency range. As the size of electronic devices decreases, multi-layer common mode noise filters require smaller, lighter, and more compact designs to adapt to the trends of miniaturization and integration.
