Myelofibrosis or osteomyelofibrosis is a myeloproliferative disorder which is characterized by proliferation of abnormal clone of hematopoietic stem cells. Myelofibrosis is a rare type of chronic leukemia which affects the blood forming function of the bone marrow tissue. The disorder is found to occur mainly in the people of age 50 or more and shows no symptoms at an early stage. The common symptoms associated with myelofibrosis include weakness, fatigue, anemia, splenomegaly (spleen enlargement) and gout. However, the disease progresses very slowly and 10% of the patients eventually develop acute myeloid leukemia. Treatment options for myelofibrosis are mainly to prevent the complications associated with low blood count and splenomegaly.
