Nanopore sequencing is used in the sequencing of biopolymers such as polynucleotides in the form of DNA or RNA and other components. In addition, nanopore sequencing is a technology that enables analysis of single molecule DNA or RNA that can be sequenced without the need for polymerase chain reaction amplification or chemical labeling of the sample. This technology uses minute changes in electric current across the nanopore immersed in a conducting fluid with voltage applied when a moving nucleotide (or DNA strand) passes through it. This helps to sequence any DNA/RNA fragment length to characterize more genetic variation. Furthermore, the technology helps in generating content-rich data, including methylation. The data generated is for real time, and helps in giving rapid insights.. It is a scalable technology that ranges from portable devices to ultra-high throughput desktop devices that are aiding in sequence as per requirement.
