Peripherally inserted central catheters (PICC) are commonly known as percutaneous indwelling central catheters or PICC line. PICC lines are often used in antibiotic therapy, chemotherapy, or total parenteral nutrition or for administration of drugs that should not be given peripherally. PICC line is inserted in the body percutaneously at peripheral site and extended up to superior vena cava. It is an alternative to central venous catheter, which is inserted through major veins such as jugular or femoral. Generally, PICC line is appropriate for patients who have undergone more than two weeks of treatment. These catheters are well-sustained by neonates, with dwell time of two to three weeks. However, dwell time varies case to case. There could be risk of complications such as phlebitis, bleeding, catheter occlusion due to holding of PICC for more than a month. Strict infection control procedures should be followed before insertion of PICC line to reduce the risk of infection.
