Non-invasive diagnosis is a procedure of identifying a disease without or with minimal incision of the body. These methods involve different techniques such as identifying genetic structure, biomarkers, changes in molecular biology, along with imaging technologies. Cancer is a disease related to genetic alteration of the cells and therefore causing uncontrolled growth and forming tumor like structure. Imaging is the preferred method of cancer detection but cannot have genetic access; on the other hand biopsies which have genetic access are complicated and difficult to perform repetitively during the course of cancer diagnosis and therapy. Therefore newer techniques developed in lines with non invasive diagnosis such as molecular diagnosis, serum based immunoassays and chemical tests to identify chemical components in the body especially from blood and urine. All these procedures are performed either with non-surgical or minimal surgical procedures; therefore these non-invasive cancer diagnostic techniques are becoming more and more popular among healthcare practitioners.
