The global Nucleotide Residue market size is predicted to grow from US\$ 71.91 million in 2025 to US\$ 101 million in 2032; it is expected to grow at a CAGR of 5.1% from 2026 to 2032.

Nucleotide residue is a by-product produced during the production of nucleotides. Nucleotides are a class of compounds composed of three substances: purine base or pyrimidine base, ribose or deoxyribose, and phosphate. They have extremely important physiological functions in organisms, such as being raw materials for nucleic acid synthesis and participating in energy metabolism. After industrial production of nucleotides (for example, through microbial fermentation), the remaining substance is nucleotide residue.

Nucleotide residue contains a certain amount of nucleotide components that have not been completely extracted, as well as bacterial proteins and residual culture medium components during microbial fermentation. Among them, bacterial proteins are accumulated by the large-scale reproduction of microorganisms during the fermentation process, and their content is relatively high. The culture medium components include the residual parts of some inorganic salts, carbon sources (such as sugars) and nitrogen sources (such as amino acids).

Nucleotide residue is usually a solid powder or granular substance. The color may vary depending on the production process and raw materials, generally ranging from light yellow to dark brown. It has a certain degree of hygroscopicity. If the ambient humidity is high during storage, it may absorb moisture and form lumps.

United States market for Nucleotide Residue is estimated to increase from US\$ million in 2025 to US\$ million by 2032, at a CAGR of % from 2026 through 2032.

China market for Nucleotide Residue is estimated to increase from US\$ million in 2025 to US\$ million by 2032, at a CAGR of % from 2026 through 2032.

Europe market for Nucleotide Residue is estimated to increase from US\$ million in 2025 to US\$ million by 2032, at a CAGR of % from 2026 through 2032.
