Objectives for imaging cleared specimen refer to a microscope objective used in microscopy imaging, which is specially designed for imaging cleared specimens, with its high NA, large field-of-view, and ultra-long working distance, this objective enables observation of large samples and whole organs with exceptional clarity and throughput. Clearing is a method of making tissue specimens transparent, usually by removing opaque components (such as fat) in the tissue, so that light can penetrate deep into the tissue for better observation of internal structures. This technology is often used in biology, neuroscience and other fields to observe complex three-dimensional structures, such as brain tissue or other organs.
