The global Overfrequency Ultrasonic Transducer market size is predicted to grow from US$ 145 million in 2025 to US$ 187 million in 2031; it is expected to grow at a CAGR of 4.3% from 2025 to 2031.

An ultra-high frequency ultrasonic transducer is a device that uses the piezoelectric effect of materials to convert electrical energy into mechanical vibrations. When an electrical signal with a frequency equal to the natural oscillation frequency of the piezoelectric chip is applied to the electrode, the piezoelectric chip will resonate, vibrate and transmit ultrasonic energy in a fixed direction, thereby converting the electrical signal into an ultrasonic signal. Conversely, when the resonance disk receives ultrasonic waves, the piezoelectric chip is compressed and vibrates, thereby converting the sound wave signal into an electrical signal. An ultra-high frequency ultrasonic transducer is usually composed of a housing, a matching layer (i.e., an acoustic window), a piezoelectric ceramic disc transducer, a backing, and a lead-out cable. Among them, the piezoelectric ceramic disc transducer is the core component, responsible for converting electrical energy into mechanical energy.

United States market for Overfrequency Ultrasonic Transducer is estimated to increase from US$ million in 2024 to US$ million by 2031, at a CAGR of % from 2025 through 2031.
