Packet firewall devices are network security appliances that operate at the network layer or transport layer of the OSI model. They function by inspecting individual data packets as they pass through the network. These devices analyze key elements of the packets, such as source and destination IP addresses, port numbers, and the type of protocol being used. Based on a set of predefined rules and policies, packet firewall devices decide whether to allow a packet to pass through the network or to block it. Their primary purpose is to protect a network from unauthorized access, malicious traffic, and security threats by filtering out potentially harmful packets, thereby enhancing the overall security posture of the network infrastructure.
