HJT Solar Cell is a solar cell whose structure is composed of two or more heterogeneous semiconductors of different materials. These heterogeneous semiconductor materials have differences in energy gaps, electron affinities, etc., forming an electrical potential barrier that helps improve the efficiency of solar cells. The production of HJT solar cells is mainly divided into four links: cleaning and texturing, amorphous silicon film deposition, TCO film deposition and metallization. PECVD is the most popular amorphous silicon film deposition equipment for HJT solar cells.

The global PECVD for HJT Solar Cells market size is projected to grow from US\$ million in 2024 to US\$ million in 2030; it is expected to grow at a CAGR of % from 2024 to 2030.

PECVD technology uses glow discharge plasma to decompose gas source molecules such as silane to achieve the preparation of amorphous silicon thin films. The principle is: the electrons in the reaction gas accelerate to gain energy in the external electric field and undergo a primary reaction with the reaction gas, causing the gas molecules to ionize and decompose, thereby forming plasma. A large number of chemically active ions, neutral atoms and molecular products in the plasma are transported to the film growth surface, while other products are released, ultimately forming a film.
