Pediatric high flow nasal cannula is a new non-invasive ventilation therapy that appears to be well tolerated in children. Recently, there has been a significant increase in the use of HFNC in pediatric and adult care settings. In recent decades, HFNC has been widely used in adult patients. Acute hypoxic respiratory failure, post-extubation support, preoxygenation before intubation or during bronchoscopy, postoperative respiratory failure, and acute pulmonary edema are indications with evidence in adults. Many pediatric studies have included patients with acute bronchiolitis. Other indications, such as asthma, sleep apnea, pneumonia, transport of critically ill patients, and post-extubation respiratory support, have been studied. Oxygen therapy using a heated, humidified high-flow nasal cannula (HHHFNC) provides warm, humidified oxygen at flow rates in excess of minute volume requirements. High oxygen concentration and positive intrathoracic airway pressure can be achieved at flow rates of 1 to 2 L/kg/min. Since its introduction to neonatal intensive care more than 20 years ago, HHHFNC therapy has been used more widely to help neonates, children and adults with severe respiratory distress avoid intubation or reintubation. Nasal cannulas with smaller pointed tips are used in pediatrics, carrying 0.5-1 liters of oxygen per minute for newborns, 1-2 liters of oxygen per minute for infants, and 1-4 liters of oxygen for older children. These pediatric nasal cannula devices are softer and gentler on the delicate facial skin of babies. These devices are made of lightweight tubes that can be easily wrapped around a patient's ear. One end of the tube goes into the nostril, while the other connects to the oxygen concentrator. There is a small chance of mucus blocking the airway.
