## Abstracts

The global Phosphosilicate Glass market size is predicted to grow from US\$ 456 million in 2025 to US\$ 667 million in 2031; it is expected to grow at a CAGR of 6.5% from 2025 to 2031.

The impact of the latest U.S. tariff measures and the corresponding policy responses from countries worldwide on market competitiveness, regional economic performance, and supply chain configurations will be comprehensively evaluated in this report.

Phosphosilicate Glass (PSG) is a type of silicon dioxide ( $\text{SiO}_2$ ) doped with phosphorus pentoxide ( $\text{P}_2\text{O}_5$ ), commonly used in semiconductor manufacturing as a dielectric layer for insulation, planarization, and impurity gettering. Produced through processes like chemical vapor deposition (CVD), PSG exhibits a low dielectric constant and softens at elevated temperatures, enabling surface reflow and smoothing. Its phosphorus content helps trap mobile ions such as sodium, enhancing the reliability of integrated circuits. PSG is frequently employed in CMOS and MEMS fabrication, and its properties can be further tailored in variants like borophosphosilicate glass (BPSG) for improved film stress control and reflow behavior.

Phosphosilicate Glass (PSG) is characterized by key parameters including phosphorus content (typically 1–10 wt%  $\text{P}_2\text{O}_5$ ), which influences its reflow temperature (850–1050°C), dielectric constant (around 3.5–4.5), and ion-gettering capability. Higher phosphorus levels enhance reflow and gettering efficiency but also increase moisture absorption, necessitating protective capping layers in some applications. PSG is typically deposited via LPCVD, PECVD, SACVD, or spin-on methods, with film thickness ranging from hundreds of nanometers to several microns. Its etch rate is higher than pure silicon dioxide, making it easier to pattern during semiconductor

fabrication. These parameters collectively determine PSG's effectiveness in microelectronics, particularly in dielectric, passivation, and planarization roles.
