Photolithography services create photomasks and use them to etch or engrave patterns on semiconductor substrates. Photolithography is a semiconductor manufacturing process that is used to remove parts of a thin-film selectively, or to etch away the majority of a flat substrate. Typically, this microfabrication process uses a photomask for integrated circuit (IC) fabrication. Photomasks are made of high-purity glass or quartz, and contain precise images of ICs or chips that are transferred optically onto

semiconductor wafers. By using a powerful, projected light and a high-aperture lens, photolithography services cast an image of the device's design onto a silicon wafer coated with a photoresist, a light-sensitive material that is then removed.
