The picometer-accurate displacement laser interferometer is a high-precision measuring instrument used to measure the small displacement or deformation of an object. It is

based on the principle of laser interference, by dividing the laser into two beams, irradiating them on the object to be measured respectively, and recombining the two beams of reflected light, and measuring the displacement of the object to be measured through the interference phenomenon. A picometer is an extremely small unit of length equal to one trillionth of a millimeter (10^{-12} meters). The displacement laser interferometer with picometer precision can achieve the measurement accuracy of the displacement of the object to the picometer level, that is, the precision of the displacement of the object can reach the level of one billionth of a millimeter. A picometer-precision displacement laser interferometer is usually composed of a laser light source, a beam splitter, a mirror, an interferometer, a detector, and a signal processing system. When the object to be measured has a slight displacement, one of the optical paths will change, and the displacement of the object can be calculated by measuring the phase difference of the interfering light. Picometer-precision displacement laser interferometers are widely used in micro-nano technology, optical manufacturing, material science, biomedicine and other fields. It can be used to measure the deformation of micro components, the thickness change of thin films, the displacement of small vibrations, etc. Its high precision and non-contact nature make it an indispensable measurement tool in research and engineering applications.
