The polarizing beam splitter prism is formed by coating the multi-layer film structure on the inclined surface of the right angle prism, and then gluing it into a cubic structure, using the property that the transmittance of P-polarized light is 1 and the transmittance of S-polarized light is less than 1 when the light is incident at Brewster's angle. After the light passes through the multilayer film structure at Brewster's angle for many times, it reaches an optical element in which the P-polarized component is completely transmitted, and most of the S-polarized component is reflected (at least 90% or more).
