The global Polymyxin market size is predicted to grow from US\$ 55.37 million in 2025 to US\$ 46.07 million in 2032; it is expected to grow at a CAGR of -2.7% from 2026 to 2032.

Polymyxin is a class of polypeptide antibiotics produced by fermentation of *Paenibacillus polymyxa*. In the agricultural sector, it is primarily used for the prevention and treatment of bacterial diseases in livestock and poultry, particularly infections caused by Gram-negative bacteria affecting the gastrointestinal and respiratory systems. Major types include Polymyxin B and Colistin, which act by binding to lipopolysaccharides in the bacterial outer membrane and disrupting membrane permeability, leading to rapid bactericidal effects. In large-scale farming systems, polymyxins are applied to control pathogens such as *Escherichia coli* and *Salmonella*, contributing to improved survival rates, feed efficiency, and production stability. With increasingly stringent antimicrobial regulations in agriculture, the industry structure and market positioning of polymyxins are undergoing significant transformation. In 2025, global Polymyxin production reached approximately 3773 MT and price is about 15 USD/kg. The average gross profit margin of this product is 1%.

With the continuous expansion of intensive and large-scale farming systems, pressure on animal disease prevention and control remains significant, particularly for Gram-negative bacterial infections in swine and poultry production. This sustains baseline demand for polymyxins in therapeutic applications. In emerging economies, livestock capacity expansion and rising demand for animal protein further emphasize the importance of disease management and production efficiency. Under regulatory frameworks that still allow therapeutic use, polymyxins maintain a defined market niche. Farmers' focus on reducing mortality and stabilizing production performance also reinforces reliance on effective antibacterial agents.

The global spread of antimicrobial resistance, especially polymyxin resistance genes, has triggered strict regulatory scrutiny. In many regions, the preventive or growth-promoting use of polymyxins in agriculture has been prohibited, restricting application to therapeutic purposes only. Rising public awareness of food safety and antibiotic residues encourages the transition toward reduced-antibiotic or antibiotic-free production systems. Moreover, alternative solutions such as probiotics, plant extracts, and vaccination technologies are gaining maturity, gradually diverting demand from conventional antibiotics and placing structural pressure on the polymyxin market.

Downstream demand is concentrated in large-scale pig farms, broiler production enterprises, and aquaculture operations. As farming operations become more standardized and corporatized, medication management is increasingly regulated and precise, shifting from broad application to targeted therapeutic use. Intestinal health management has become a central theme, integrating antimicrobial treatment with optimized feeding and biosecurity systems. In export-oriented agricultural countries, stricter compliance requirements are driving demand toward higher-quality, low-residue products. The adoption of digital farming and disease monitoring technologies further enhances controlled and data-driven antibiotic usage.

Agricultural polymyxins are mainly produced through microbial fermentation. Key upstream components include strain selection, fermentation media formulation, and purification processes. Strain stability and fermentation efficiency are critical to quality and cost control. The balance of carbon sources, nitrogen sources, and trace elements in the culture medium significantly influences yield, while solvents and adsorption materials used in purification affect final purity and safety. As environmental regulations tighten and production standards rise, upstream manufacturers must strengthen emission control and quality management systems to ensure supply chain stability and regulatory compliance.
