Pre-emergent broadleaf herbicide is a type of chemical herbicide applied before weed seeds germinate or sprouts emerge from the soil, specifically used to prevent the growth of broadleaf weeds. This type of agent forms a chemical barrier on the soil surface, interfering with cell division, enzyme activity or root bud development during weed seed germination, thereby inhibiting the emergence of weed seeds into seedlings. Pre-emergent broadleaf herbicides are usually sprayed before sowing or before seedlings emerge from the soil after sowing, and are activated by rain or irrigation. They are widely used in crop fields such as corn, soybeans, wheat, cotton, lawns and orchards, and have the advantages of preventing and controlling early weeds and reducing later human intervention. Common active ingredients include metolachlor, fomesafen, thifensulfuron, etc. Some products are used in conjunction with post-emergence herbicides to build a more complete weed control system. Pre-emergence broadleaf herbicides play an important role in controlling resistant weeds, reducing the total amount of herbicides used and improving field cleanliness. They are particularly suitable for tillage systems with early weed emergence, continuous cropping or short management cycles.
