Rack thermal management plays a key role in the general reliability of a server system. Maintaining the temperature within racks and enclosures is critical to the correct functioning and survival of the circuits that operate within them. It is essential to ensure the heated air within the enclosure remains at a temperature of no more than 85 degree F to help protect sensitive equipment.

There are two approaches to securing an adequate internal enclosure temperature for the successful operation of the components enclosed: Passive and Active rack thermal management. Passive makes use of the ability of a properly configured system to ventilate through natural convection. In certain cases, however, the use of fans to force air through an enclosure is necessary to maintain the desired internal temperature.
