The evaporator is an important component among the four major components of refrigeration. The low-temperature condensed liquid body exchanges heat with the outside air through the evaporator, vaporizes and absorbs heat, achieving the effect of refrigeration. It mainly consists of two parts: a heating chamber and an evaporation chamber. The heating chamber provides the heat required for evaporation to the liquid, promoting its boiling and vaporization; The evaporation chamber completely separates the gas-liquid phases. The steam generated in the heating chamber contains a large amount of liquid droplets. After entering the larger evaporation chamber, these liquids can be separated from the steam through their own condensation or defoaming device. Blow expansion evaporators are mainly used for freezing and refrigeration.
