Resistive loss absorbing materials are materials that can effectively absorb electromagnetic waves, and their main absorption mechanism is resistive loss. When electromagnetic waves pass through conductive materials, induced currents are generated in the materials, which are then converted into heat energy and absorbed. Specifically, when electromagnetic waves are injected into resistive loss absorbing materials, free carriers (such as electrons or ions) inside the material will move under the action of the electric field, and resistance will be generated during the movement, thereby converting electromagnetic energy into heat energy and consuming it. Therefore, the greater the conductivity of the absorbing material, the greater its resistive loss and the better the electromagnetic wave absorption effect.

The global Resistive Loss Type Absorbing Material market size is projected to grow from US\$ million in 2024 to US\$ million in 2030; it is expected to grow at a CAGR of %from 2024 to 2030.
