The reverse osmosis diaphragm is generally a semi-permeable membrane, which can effectively remove microscopic pollutants such as dissolved substances, suspended substances, bacteria and viruses in water, thereby providing a clean water source.

The working principle of reverse osmosis membrane is based on the process of osmosis and reverse osmosis. When the concentrations of the two solutions are

different, the process of separating the less concentrated solute molecules in the solution from the higher concentrated solution through a semipermeable membrane is called osmosis. Reverse osmosis is the process of reversely pushing water molecules from a high-concentration solution to a low-concentration solution by applying higher pressure. In the reverse osmosis membrane, water molecules can pass through the tiny pores of the membrane, but most of the solute molecules and microorganisms are blocked on the other side of the membrane, thereby achieving water purification and removal of pollutants.
