The rotation component contains important wavefield gradient information and is a key element in seismic wavefield reconstruction, but it was often ignored in different seismological applications due to the lack of stable and high-sensitivity rotating measurement instruments in the past. The fiber optic rotating seismometer is the first to break the measurement instrument The rotational seismograph that lacks difficulties and is the first to be commercialized is also the most promising device for direct measurement of seismic wave rotation. The fiber optic rotational seismograph is based on the Sagnac effect and relies on mature fiber optic gyroscope technology to achieve the measurement of the rotational component of vibration. It has Pure photoelectric sensing has the advantage of not being affected by translation; and it can realize the miniaturization of equipment on the basis of high sensitivity and broadband rotation measurement, which is conducive to the application of rotation measurement. Therefore, fiber optic rotation seismographs and traditional seismic The instruments will complement each other, realize the observation of six components of rotation and translation (6C), better extract the characteristics of the seismic wave field, improve the ability of vibration monitoring, and effectively improve the application of source process inversion, underground structure imaging and earthquake damage mechanism research.
