Scanning electron microscope imaging lens, as one of the core components of scanning electron microscope (SEM), plays a vital role. The scanning electron microscope imaging lens is a key part of the scanning electron microscope for receiving and forming the surface image of the inspected object. It receives the signal (such as secondary electrons, backscattered electrons, etc.) generated by the electron beam scanning the surface of the sample and converts it into a visual image for researchers to observe and analyze.

The scanning electron microscope imaging lens is usually composed of multiple complex lenses and detectors, which work together to complete the signal reception, conversion and imaging process. Among them, the electron gun is used to generate a high-energy electron beam, and the electromagnetic lens is used to focus the electron beam and control its scanning path. The detector is responsible for receiving the signal generated by the interaction between the electron beam and the sample and converting it into an electrical signal.

The global Scanning Electron Microscope Imaging Lens market size is projected to grow from US\$ 571 million in 2024 to US\$ 970 million in 2030; it is expected to grow at a CAGR of 9.2% from 2024 to 2030.
