## Abstracts

The global Segmented PID Controller market size is predicted to grow from US\$ million in 2025 to US\$ million in 2032; it is expected to grow at a CAGR of %from 2026 to 2032.

The segmented PID controller is a special PID (proportional-integral-differential) controller, which is characterized by dividing the control process into different stages or intervals according to the characteristics of the controlled object or the control requirements, and setting different PID control parameters for each stage or interval. This controller design is intended to improve the flexibility and adaptability of the control system to better meet the needs of complex control tasks.

In the segmented PID controller, the PID parameters (proportional coefficient  $K_p$ , integral coefficient  $K_i$  and differential coefficient  $K_d$ ) of each stage or interval are set independently. This means that in different control stages, the controller can adopt different control strategies as needed to achieve more accurate and stable control effects.

The application of segmented PID controllers is very extensive, especially in systems that require precise control and the control process has obvious stage characteristics. For example, in a temperature control system, when the temperature needs to change quickly from one set value to another, PID parameters with higher proportional gain and differential gain can be used to speed up the response; when the temperature is close to the target value, it can be switched to PID parameters with lower proportional gain and higher integral gain to reduce steady-state error and improve control accuracy.

In addition, the segmented PID controller can also be combined with other control

strategies, such as fuzzy control, neural network control, etc., to further improve the performance and adaptability of the control system. This combination can make full use of the advantages of various control strategies to achieve more complex control tasks.
