Semi-active suspension refers to a controllable suspension system which senses the road condition and body attitude by sensors, adjusts the damping parameters, and thus improves the ride comfort and stability of the vehicle. Traditional suspension parameters are difficult to change once selected, so an optimal compromise is usually sought to determine the parameters during the design process. That is, the performance of the car is the best only under certain conditions; Once the working condition changes (such as road surface changes, acceleration, braking, and steering state changes when the car is driving), its performance will deteriorate, which means that the traditional suspension is difficult to meet the requirements of comfort and stability at the same time, thus limiting the further improvement of the car's performance. With the development of technology and the improvement of manufacturing process, the application of controllable suspension in automobiles becomes possible. The suspension system adopts intelligent control, so that it can have different performance according to different road conditions, so as to coordinate the contradiction between ride comfort and stability, and also provide the possibility to expand the traditional suspension function. Semi-active suspension is such a controllable suspension, which does not change the suspension stiffness but only changes the suspension damping to adjust the performance of the suspension, so it is also called damping controllable suspension. Its structure is relatively simple, the cost is low, the performance is good, has a wide range of application prospects.

The global Semi-Active Suspension market size is projected to grow from US\$ million in 2024 to US\$ million in 2030; it is expected to grow at a CAGR of %from 2024 to 2030.
