The global Single Port Surgical Platforms market size is predicted to grow from US\$ 53.73 million in 2025 to US\$ 204 million in 2032; it is expected to grow at a CAGR of 21.1% from 2026 to 2032.

A single-port surgical platform is a versatile medical device capable of performing both routine and complex surgical procedures. It consists of three main components: a surgeon console, a patient-side surgical platform, and a high-definition three-dimensional imaging system. The surgeon sits at the console and intuitively controls the robotic arms and the attached surgical instruments on the patient-side platform, performing minimally invasive procedures while viewing the operative field through high-resolution 3D images.

The single-port surgical platform supports multiple surgical techniques, including laparoscopic surgery, minimally invasive surgery, and percutaneous interventional procedures. It helps reduce surgical trauma, shorten postoperative recovery time, and improve overall surgical efficiency and quality.

Compared with conventional single-port laparoscopic surgery, single-port surgical robots enter the patient's body through a single small incision, can expose the surgical field and switch instruments flexibly without the need for an assistant, and enable more precise and technically demanding intraoperative maneuvers, thereby delivering an improved treatment experience for patients.

As a core innovative device in the field of minimally invasive surgery, the technological evolution and market expansion of Single Port Surgical Platforms are deeply bound to the global trend of medical transformation towards precision and humanization, with

multiple key factors jointly driving their continuous upgrading and clinical popularization. The ultimate pursuit of minimally invasive efficacy and patient experience in clinical practice is the primary driving force. Compared with traditional multi-port minimally invasive surgery, this platform completes complex operations through a single small incision, which can minimize damage to abdominal wall tissue and stimulation of nerves and blood vessels. At the same time, the incision can be hidden in natural folds to achieve an aesthetic effect, significantly reducing postoperative pain and shortening the recovery cycle for patients, which is in line with the needs of modern medical humanistic care and efficient diagnosis and treatment. Iterative breakthroughs in technological innovation empower and enhance its efficiency. The integrated application of 3D high-definition visualization systems, articulating intelligent instruments and robot-assisted technology effectively solves the problems of limited operation space and easy instrument interference in single-port surgery, improves surgical precision and operational flexibility, and promotes its application scenarios from routine procedures to more complex surgical fields. Policy support and industry orientation further strengthen development momentum. The R&D support for minimally invasive medical devices and localization substitution policies in various countries force enterprises to increase technological investment. Meanwhile, the pursuit of diagnosis and treatment efficiency and reputation by medical institutions also prompts tertiary hospitals to take the lead in deploying and promoting such platforms, accelerating their clinical penetration. In addition, the popularization of global minimally invasive surgical technology and the improvement of training systems have lowered the threshold for doctors' operations, laying a talent foundation for the large-scale application of single-port surgical platforms.

Despite the prominent clinical value and market potential of single-port surgical platforms, their technological implementation and industry promotion still face many challenges that need to be overcome. Operational difficulty and technical barriers constitute core constraints. Under the single-port mode, all instruments need to enter the body cavity through the same incision, which is prone to the 'chopstick effect' of mutual instrument interference, putting extremely high requirements on doctors' hand-eye coordination and counter-intuitive reverse operation thinking. Moreover, the problem of blind spots in the field of vision in complex surgical scenarios cannot be completely avoided, limiting its application in procedures such as large tumor resection and complex adhesion lysis. The imbalance between cost and accessibility is prominent. The R&D and manufacturing costs of high-end single-port surgical platforms and supporting consumables are high. In addition, continuous investment is required for postoperative maintenance and doctors' special training, resulting in high equipment prices. Only a few tertiary hospitals have the purchasing capacity, while primary medical

institutions are difficult to popularize, exacerbating the uneven distribution of medical resources. Market competition and patent barriers increase industry pressure. The global market is monopolized by a few leading enterprises, and core technologies and patent layouts form high entry thresholds. Moreover, the inconsistent equipment specifications and operating systems of different manufacturers increase the difficulty of clinical adaptation and technological promotion. In addition, there are still shortcomings in clinical application boundaries and safety control. The adaptability to special patient groups and complex anatomical structures is insufficient, the emergency conversion capacity in case of intraoperative emergencies is limited, and relevant industry standards and operating specifications are not yet fully improved, further restricting the breadth and depth of its clinical application.
