## Abstracts

The global Skin Burn Model market size is predicted to grow from US\$ 301 million in 2025 to US\$ 424 million in 2032; it is expected to grow at a CAGR of 5.2% from 2026 to 2032.

In 2025, global Skin Burn Model production reached approximately 3.84 M Units. The average price is approximately \$80. Skin burn models are simulation models or prosthetic systems used in medical education, nursing training, emergency and disaster medicine drills. They are specifically designed to simulate different types and depths of skin burn wounds to support burn assessment, grading, treatment procedures, and clinical decision-making training.

### Gross Profit Margin Levels

From the manufacturing perspective, the gross profit margin of skin burn models exhibits a typical 'three-stage' pattern: Structural display models (rigid PVC/resin cross-sectional models) are closer to traditional teaching aid manufacturing, with a higher proportion of material and mold amortization and heavier channel discounts, and the gross profit margin is usually in the range of 25%–40%; Medium-to-high fidelity burn prostheses/patterns (silicone/PU, reusable) have relatively controllable material costs, and their value mainly comes from the realism of appearance, hand-painting, and process stability, with a gross profit margin commonly ranging from 40%–60%; while rapidly consumable products (wound stickers/transfers, glues/cleaners/disposable accessories) have stronger 'consumable attributes' and repurchase logic, with low unit material costs, but stronger dependence on channels and brands, and mature manufacturers can further explore the gross profit margin to 55%–70% after scaling up. Ultimately, gross profit margins are often determined by three factors: first, realism and reusability (directly impacting customers' 'unit training cost' and repeat purchases); second, channel structure (direct sales to training centers vs. distributor levels); and

third, the degree of customization (customized scenarios for military/police/disaster drills, skin tone gradations, exudation/odor features, etc., significantly increase the selling price, but also raise delivery costs and after-sales requirements).

## Industry Drivers

The growth momentum of skin burn models essentially stems from the systematic remedial training of 'high-risk, low-frequency skills' within the medical and emergency response systems. Firstly, the global medical simulation industry is in a period of expansion, driven by factors such as patient safety, standardization of clinical skills, personnel shortages, and training efficiency. Market research institutions generally predict high growth rates. Secondly, burn treatment is characterized by a short window of opportunity, a long treatment chain, and high costs associated with complications. However, real-case exposure during routine teaching and clinical rotations is not consistent, prompting universities and hospitals to rely more on repeatable simulation training. Product forms such as patch-type burn wounds, wearable trauma kits, and rapidly deployable injury stickers significantly lower the barrier to scenario setup and increase the frequency and coverage of drills (from ward nurses to pre-hospital emergency care, and multi-department disaster drills). Finally, the procurement side is shifting from 'buying models' to 'buying systems': combining burn models with OSCE assessments, trauma courses (TCCC/ATLS/ETC), pre-hospital-in-hospital joint drills, and even VR digital patients to form a quantifiable training and certification closed loop. This will increase the budget for individual projects and make it easier for manufacturers with the capability to combine 'products + courses + consumables + services' to expand their market share.
