A smart soil sensor is a device that uses physical, chemical, and biological principles to collect real - time environmental parameters of soil, such as moisture, nutrients, temperature, and pH value. It usually consists of a sensing element, a signal conditioning circuit, a data acquisition module, and a wireless communication module. The sensing element is the core part for detecting soil parameters. The signal conditioning circuit is used to amplify, filter, and convert the weak electrical signals output by the sensing element to make them meet the requirements of the data acquisition module. The data acquisition module collects and digitizes the conditioned signals. The wireless communication module is responsible for transmitting the data to a remote server or terminal for users to view and analyze. In addition, the sensor housing is made of materials with good corrosion resistance, weather resistance, and mechanical strength to ensure stable long - term operation.
