Spray Type deaerator is a cylindrical vessel used for the removal of dissolved gases from the feed water. Basically, the removal of dissolved gases is done by either decreasing the pressure or increasing the temperature inside the deaerator. The feed water fed into the deaerator will pass on through the vented section where the water will experience high steam which allows the feed water to remove dissolved gases. The spray type deaerator consists of a spray nozzle, baffle, preheating section, and deaeration section. First of all, the feed water introduced into the deaerator is flown through the spray nozzle inside the vessel. There is a steam supply connected to the vessel which is used to heat the feed water. Then, the water exposed to steam is sent

to the preheating section. In the preheating section, the water is heated by steam until the temperature of the water reaches its saturation point. At this high temperature, the feed water containing dissolved gases will be eliminated. The high-temperature water converted to steam is sent to the deaeration section. In the deaeration section, steam and water droplets will be separated. The separated dissolved gases are escaped out through the Air vent. And the water droplets free from gases are collected at the bottom of the vessel. The deaerator boiler feed water is fed to the boiler by using a pump. This water is used as the feed water to the boiler which helps in avoiding the corrosion.
