Spraying corn husk is a byproduct of corn processing, which is produced during the deep processing of corn. When producing products such as corn starch or corn ethanol, corn husks are produced after a series of processes such as soaking, crushing, and separation. These corn husks are originally rough and have relatively simple nutritional components. Spraying corn husks are products obtained by spraying corn soaking liquid (mainly containing amino acids, proteins, a small amount of starch and other nutrients) onto corn husks, and then drying and other processes.

Spraying corn husks contain a certain amount of protein, because the soaking liquid added during the spraying process is rich in nutrients such as protein, and the content is generally around 18% - 22%. At the same time, it also contains more fiber components, including cellulose, hemicellulose, etc., which help the physiological functions of animal intestinal peristalsis. In addition, it also contains a small amount of starch and fat, which can provide animals with a certain amount of energy.

Spraying corn husks are a relatively high-quality feed raw material. It is widely used in livestock and poultry farming. For example, adding sprayed corn husks to pig feed can provide pigs with certain nutrition, especially protein and fiber. For ruminants such as cattle and sheep, its fiber content can promote the growth and fermentation of rumen microorganisms, helping to improve the digestibility of feed. In addition, in some industrial fermentation processes, spraying corn husks can also be used as one of the components of microbial culture medium, using the nutrients it contains to cultivate microorganisms, but this use is relatively less extensive than feed use.
