Sputtering Equipment for Ceramic Substrate first evacuates the chamber to a high vacuum to minimize the partial pressure of all background gases and potential contaminants. After reaching the base pressure, the sputtering gas containing the plasma flows into the chamber and the total pressure is regulated using a pressure control system. To initiate plasma generation, a high voltage is applied between the cathode (usually located directly behind the target) and the anode (usually connected to the chamber as electrical ground). Electrons present in the sputtering gas are accelerated away from the cathode, causing collisions with nearby sputtering gas atoms. These collisions cause electrostatic repulsion that 'knocks out' electrons from the atoms of the gas, causing ionization. Positive sputtering gas atoms are now accelerated towards the negatively charged cathode, resulting in energetic collisions with the target surface. Each of these collisions can cause atoms from the target surface to be ejected into the vacuum environment with sufficient kinetic energy to reach the substrate surface. In order to promote as many energetic collisions as possible - thereby increasing deposition rates - the gas is usually selected to be a high molecular weight gas such as argon or xenon. Gases such as oxygen or nitrogen can also be introduced into the chamber during film growth if a reactive sputter deposition process is required.
