A Superconducting Magnetic Resonance Instrument (SMRI) is a type of scientific instrument that uses superconducting materials to generate high-intensity magnetic

fields for the purpose of studying materials and biological samples.

The principle behind an SMRI is based on Nuclear Magnetic Resonance (NMR), a technique that uses the magnetic properties of atomic nuclei to study the structure and properties of molecules. In an SMRI, the sample is placed inside a strong magnetic field generated by superconducting coils, which are maintained at very low temperatures using liquid helium.

The magnetic field induces a magnetic moment in the atomic nuclei of the sample, which is then excited using radio frequency pulses. The resulting resonance signals are detected and processed to generate a spectrum that provides information about the chemical structure and physical properties of the sample.

SMRIs are used in a variety of fields including chemistry, biology, materials science, and physics. They are particularly useful for studying complex molecules such as proteins, nucleic acids, and polymers, and for characterizing the physical properties of materials such as superconductors and magnetic materials.
