Surgical drainage tubes are implants that allow fluid and/or gas to drain from a wound or body cavity, and are typically made of rubber material. Surgical drainage tubes can aid in wound healing by removing inflammatory mediators, bacteria, foreign bodies, and necrotic tissue. Not only does it relieve the pressure that causes pain, thereby reducing morbidity and inflammation, it can also monitor potential complications by easily sampling fluids during the healing process. Surgical drainage tubes can generally be divided into two types, active drains and passive drains. An active drain is a closed system that collects fluid into a reservoir. The storage tank prevents saturation of the bandage material, reduces the risk of ascending infection, and prevents hospital staff or other patients from being exposed to contaminated fluids. Passive drains are generally made of latex, polypropylene or silicone rubber. Compared with active drains, passive drains are easier to place and less expensive, and are most commonly used for wound management and post-operative fluid management.
