Thermal imaging night vision telescope is a device that uses infrared detection technology to observe in low-light or no-light conditions. It does not rely on visible light, but forms images by capturing infrared radiation (heat) emitted by objects. This means that thermal imaging telescopes can be used at night or in other low-light environments, and can even see through smoke and other visual obstructions. Thermal imagers can detect and identify targets more easily than traditional night vision devices because they display temperature differences rather than relying on light reflections.

The global Thermal Imaging Night Vision Telescope market size is projected to grow from US\$ million in 2024 to US\$ million in 2030; it is expected to grow at a CAGR of %from 2024 to 2030.
