## Abstracts

According to this study, the global Thermal Interface Material (TIM) market size will reach US\$ 4146 million by 2031.

Thermal Interface Materials (TIMs) are specialized substances used to enhance thermal conductivity between two mating surfaces, typically in electronic components where efficient heat dissipation is critical. These materials fill microscopic air gaps caused by surface roughness, which would otherwise act as thermal insulators. TIMs come in a wide range of forms, including thermal gap pads, thermal greases, phase change materials, thermally conductive adhesives, and gels. The ideal TIM must exhibit a balanced combination of properties such as adhesion, viscosity, coefficient of thermal expansion (CTE), bond line thickness, reworkability, and long-term stability. However, the most crucial performance metrics are thermal conductivity and thermal contact resistance—both of which directly influence the efficiency of heat transfer between components and heatsinks.

### Evolving Materials and High-Performance Demands

As electronic devices continue to adopt denser integrated circuit (IC) designs and higher power densities, the demand for more efficient, reliable, and thermally conductive TIMs is growing rapidly. In recent years, market attention has shifted toward advanced carbon-based materials, which exhibit exceptional thermal and electrical conductivity. These include graphite, carbon nanotubes (CNTs), carbon fibers derived from pitch, and various forms of graphene. Such materials are being explored either as conductive fillers embedded in polymer matrices or as standalone thermal interface layers. Particularly, vertically aligned carbon nanotube (VACNT) arrays have been extensively researched for their unique structure and thermal properties. However, the industry still

faces technical challenges in achieving scalable growth, uniform transfer, and consistent contact resistance in real-world applications. Despite these hurdles, carbon-based TIMs show immense promise across high-end sectors such as LED packaging, base station electronics, high-performance computing, and military-grade thermal management systems.

## Market Drivers and Outlook

The TIM market is experiencing strong momentum, driven by the growth of AI servers, edge computing infrastructure, and advanced autonomous driving systems. These applications demand materials with both high thermal conductivity and long-term reliability. As a result, next-generation TIMs, particularly those leveraging carbon nanomaterials such as graphene and CNTs, are gaining traction. Graphene-based TIMs, whether in paste, film, or vertically aligned sheet form, are especially noted for their superior in-plane conductivity and low thermal resistance. Regulatory and environmental considerations are also influencing material selection, prompting a shift away from traditional silicone-based compounds toward more sustainable and high-efficiency solutions. Looking ahead, the combination of increased performance demands and ongoing innovation in nanocarbon technologies positions the TIM industry for significant growth. As application requirements become more stringent, particularly in automotive electronics and next-gen data centers, the development and commercialization of advanced TIMs will remain a key focus area for material science and thermal engineering.
