The global Thermocouple Wire market size is predicted to grow from US\$ 1019 million in 2025 to US\$ 1340 million in 2031; it is expected to grow at a CAGR of 4.7% from 2025 to 2031.

A thermocouple is a sensor for measuring temperature that consists of two dissimilar metals that are joined together at the sensing end. Different thermocouple types (e.g. J, K, T, E, etc) use different mixtures of metals in the wire. At the cjc (cold junction compensation) end, the millivolt value provided by the thermocouple represents the difference in temperature of the sensing end as compared to the cjc end (also called the reference end). Alternatively, a thermocouple wire is a temperature-measuring instrument consisting of two wires of different metals joined at each end. One junction is placed where the temperature is to be measured, and the other is kept at a constant lower (reference) temperature. A measuring instrument is connected in the electrical circuit. The temperature difference causes the development of an electromotive force (EMF) that is approximately proportional to the difference between the temperatures of the two junctions. Temperature can be read from standard tables, or the instrument can be calibrated to display temperature directly
