A reboiler is an equipment which is installed with the distillation column and its purpose is to convert the liquid which is provided by the bottom tray of the distillation column into vapours. These vapours are then returned to the distillation column. A reboiler is essentially a heat exchanger. In thermosyphon reboilers, natural circulation is obtained by using the density difference between the reboiler column bottoms liquid and the reboiler outlet vapour-liquid mixture to provide sufficient liquid head to deliver the tower bottoms into the reboiler.
