The global Thorium(IV) Fluoride market size is predicted to grow from US$ 6.59 million in 2025 to US$ 9.27 million in 2032; it is expected to grow at a CAGR of 5.1% from 2026 to 2032.

In 2024, global Thorium(IV) Fluoride production reached approximately 34.1 kg, with an average global market price of around US$ 182,000 per kg. In 2024, the global 's total production capacity of Thorium(IV) Fluoride reached 45 kg.The industry average gross profit margin of this product reached 31%.

Thorium Fluoride is a chemical compound comprising thorium and fluorine. It is highly valued in the nuclear industry for its stability, high melting point, and favorable nuclear properties. Thorium Fluoride plays a critical role in advanced nuclear reactor designs, particularly in molten salt reactors. The upstream industry of thorium tetrafluoride (ThF?) begins with the mining and smelting of thorium-bearing ores (mainly rare earth associated minerals such as monazite and tholeiite). Thorium resources are typically recovered as a byproduct of rare earth production. Through hydrometallurgical processes such as acid dissolution and extraction, thorium compounds (such as thorium nitrate and thorium hydroxide) are separated and purified from the ore. The core of this stage lies in achieving efficient separation of thorium from other rare earth elements and meeting the purity requirements of subsequent nuclear-grade feedstocks. Its supply is influenced by both the global rare earth industry landscape and radioactive mineral management policies. The midstream stage focuses on converting intermediate thorium compounds into high-purity thorium tetrafluoride nuclear materials. The key process involves hydrofluorination reactions (such as reacting thorium dioxide or thorium nitrate with anhydrous hydrogen fluoride) to generate thorium tetrafluoride powder or particles suitable for nuclear fuel cycles. This process requires strict control of impurity content (especially neutron poisons) to ensure that the product meets "nuclear-purity" standards. Thorium tetrafluoride (ThF?) is a direct precursor for the preparation of

molten salt reactor fuel salts (such as those eutectic with lithium fluoride and beryllium fluoride), and can also be used to manufacture high-end materials in non-nuclear fields such as specialty optical glass. The core downstream application of thorium tetrafluoride is as a nuclear fuel assembly for fourth-generation reactors—thorium-based molten salt reactors (TMSRs). In molten salt reactors, ThF? dissolves in the carrier molten salt and can be converted into fissile uranium-233 through neutron irradiation, achieving the thorium-uranium fuel cycle. In addition, high-purity ThF? is also used to manufacture infrared optical glass with special refractive indices, optical fibers, and laser devices. Currently, the downstream industry chain is still in the research and development verification and prototype reactor testing stage. Its large-scale development depends entirely on the maturity and commercial deployment of thorium-based molten salt reactor technology and is dominated by national nuclear energy strategies and cutting-edge science and technology policies.
