The three-chamber two-balloon tube, also known as the three-chamber two-balloon tube compression hemostasis, is a medical device consisting of three cavities and two pouches, including a three-chamber tube, a gastric balloon and an esophageal balloon. Among them, the three-chamber tube consists of a semicircular cross-section cavity and two quarter-circular cross-section cavities. The gastric balloon catheter and the esophageal balloon catheter are respectively installed in the quarter-circular cavity, while the gastric catheter is installed in the semicircular cavity. This design enables the three-chamber two-balloon tube to be flexibly and effectively used in medical operations. The main function of the three-chamber two-balloon tube is to achieve gastric and esophageal care by controlling the inflation of the balloon and the position of the catheter. In medical practice, it is often used to stop bleeding of acute bleeding in the esophagus and gastric fundus veins caused by portal hypertension, and is one of the commonly used procedures in gastroenterology. When the gastric balloon and esophageal balloon are inflated, they can produce a compression effect, thereby effectively reducing bleeding and reducing the incidence of complications such as ulceration and necrosis of the stomach and esophagus.
