The global Travelling Wave Fault Locator in Power Grid market size is predicted to grow from US\$ million in 2025 to US\$ million in 2032; it is expected to grow at a CAGR of %from 2026 to 2032.

Traveling-wave fault location is an advanced method used in the detection and precise location of faults in transmission lines and power systems. This technique utilizes the high-frequency components of fault-induced traveling waves, which propagate along the transmission line at the speed of light. By accurately capturing and analyzing these waves, utilities can significantly reduce fault location times, improve system reliability, and expedite the restoration of services.

Modern traveling wave fault recorders use a double-ended (Type D) method for fault location that does not rely on operator intervention to determine the distance to fault. Results are automatically calculated and immediately available for use. The power arc at the fault site and the resulting step change in voltage generate a traveling wave that propagates along the line in both directions to the line ends. TWS fault locators positioned at the line ends accurately tag the arrival time of the waves using GPS as a reference. These time tags are sent to a central location where they are used to calculate the distance to fault using the line length and the velocity of propagation.
