A large number of UV light curable resins have been developed to meet the stringent regulations in Europe and North America and to reduce air pollution as well as energy consumption. Their use as well as their popularity has grown significantly over the last forty years.¹ UV induced cure has many advantages over conventional cure in terms of less energy consumption and equipment space, reduced waste, less emission, higher productivity (fast cure) and lower temperature treatment. In addition, UV curable resins usually do not contain any organic solvents that have an adverse effect on the environment. The primary limitation of light-induced curing system is the limited light penetration depth which will depend on the wavelength and spectral distribution and usually does not exceed a few millimeters. This means that light induced cure is limited to inks, coatings and adhesives and in the case of adhesive applications, at least one substrate must be able to transmit light. Thus, assemblies with shaded areas will require a secondary cure mechanism.

Typical UV curable resins consist of oligomers, monomers (which act as diluents), photopolymerization initiator, coinitiators (spectral sensitizer, reducing agents etc.) and various additives such as stabilizers, antioxidants, plasticizers, and pigments. The majority of commercial light cure resins are based on free radical curing acrylic compounds (acrylates). Free radical curing compositions are the most versatile curing systems in regard to product properties and monomers / oligomers available on the market. However, free radical acrylic systems are subject to oxygen inhibition, meaning oxygen in the air can stop the molecules at the surface from polymerizing, leaving a tacky surface layer.
