Valveless pumps come without a nozzle and are controlled with a piston. The piston performs both the functions of moving fluid inside the pump and then discharging fluid out of the pump. Valveless pumps accomplish both the pumping and valving functions. The rotatory and reciprocatory function of the ceramic piston is a one-directional movement. A pump primarily changes the electrical energy into hydraulic energy, where fluids like liquids or gases are moved and churned out to provide water, irrigation, and gasoline supply etc. These pumps adjust the volume of the fluid to be dispensed. The amount of fluid displaced is low and micro-volume process applications are more viable while using valveless pumps. The piston displacement is variable and is controlled by the geometrical angle and mathematical linear calibration of the pump.
