An implanted shunt diverts CSF from the ventricles within the brain or the subarachnoid spaces around the brain and spinal cord to another body region where it will be absorbed. This creates an alternative route for removal of CSF which is constantly produced within the brain and usually restores the physiological balance between CSF production, flow, and absorption when one or more of these functions has been impaired. Valves contained within the shunt pathway act like on-off switches, opening when the differential pressure (DP) – i.e., the pressure difference across the valve – exceeds the valve's opening pressure. Valves are either set to a fixed pressure or they can be adjustable from outside the body. Accessory devices may be added to the shunt to modify valve function.

The global Ventriculoperitoneal (VP) Shunt market size is projected to grow from US\$ 204.5 million in 2023 to US\$ 299.4 million in 2030; it is expected to grow at a CAGR of 5.6% from 2024 to 2030.
